

AN AI ASSISTANT ON YOUR KNOWLEDGE BASE

A bot that says “I don't know”

100%

That is abstention on out-of-base questions. A number measured by a separate judge model over a set of 109 “golden” questions, not a promise on a slide.

THE PROBLEM

A confident liar

A generic chatbot answers with confident fiction — inventing account numbers, deadlines and office addresses that do not exist. In law, medicine, public services and finance, a confidently wrong answer costs more than an honest “I don't know”.

QUALITY MEASURED, NOT ASSUMED

Four numbers instead of assurances

A judge model runs the whole set and checks two things: did the answer convey the substance of the expected facts, and does it assert anything forbidden as fact.

"Golden" question set	109
Citation accuracy	≈99%
Fact coverage	≈97%
Out-of-base: honest "I don't know"	100%

THE KNOWLEDGE BASE IS THE PRODUCT

The bot is not smart on its own

The collector turns open chats into anonymised facts, and splitting the classifier's work into small batches cut the share landing in the “junk” catch-all from 51% to 23%. Moving a fact into the base is always a manual step by the curator, never automatic.

Messages through the collector	2.4 million
Judged relevant	28,091
Practical facts	17,284

DISCIPLINE, NOT MODEL SIZE

The secret is not the model

A strict tie to a verified base, mandatory sources and dates, measurable quality on the way out. Every model swaps for a local one with a single setting — so the whole stack can run on your own server.

The “norm” layer	re-checked every 60 days
The “practice” layer	expires by +90 days
Every model	swappable for a local one

MICODE

We will build one on your data

An assistant that answers strictly from your own base, cites a source for every fact, and honestly says "I don't know" when the answer is not there — with the question set that lets you check the claim.
